## Default Box的scale以及aspect设定

Feature maps from different levels within a network are known to have different (empirical) receptive field sizes [13]. Fortunately, within the SSD framework, the default boxes do not necessary need to correspond to the actual receptive fields of each layer. We design the tiling of default boxes so that specific feature maps learn to be responsive to particular scales of the objects. Suppose we want to use  $m$  feature maps for prediction. The scale of the default boxes for each feature map is computed as:

$$s_k = s_{\min} + \frac{s_{\max} - s_{\min}}{m - 1}(k - 1), \quad k \in [1, m] \quad (4)$$

where  $s_{\min}$  is 0.2 and  $s_{\max}$  is 0.9, meaning the lowest layer has a scale of 0.2 and the highest layer has a scale of 0.9, and all layers in between are regularly spaced. We impose different aspect ratios for the default boxes, and denote them as  $a_r \in \{1, 2, 3, \frac{1}{2}, \frac{1}{3}\}$ . We can compute the width ( $w_k^a = s_k \sqrt{a_r}$ ) and height ( $h_k^a = s_k / \sqrt{a_r}$ ) for each default box. For the aspect ratio of 1, we also add a default box whose scale is  $s'_k = \sqrt{s_k s_{k+1}}$ , resulting in 6 default boxes per feature map location. We set the center of each default box to  $(\frac{i+0.5}{|f_k|}, \frac{j+0.5}{|f_k|})$ , where  $|f_k|$  is the size of the  $k$ -th square feature map,  $i, j \in [0, |f_k|)$ . In practice, one can also design a distribution of default boxes to best fit a specific dataset. How to design the optimal tiling is an open question as well.

## Default Box的scale以及aspect设定

scale = [(21, 45), (45, 99), (99, 153), (153, 207), (207, 261), (261, 315)]	$\sqrt{21 \times 45}$ $\sqrt{45 \times 99}$	aspect = [(1, 2, .5), (1, 2, .5, 3, 1./3), (1, 2, .5, 3, 1./3), (1, 2, .5, 3, 1./3), (1, 2, .5), (1, 2, .5)]
--	--	---

Figure 2 shows the architecture details of the SSD300 model. We use conv4\_3, conv7 (fc7), conv8\_2, conv9\_2, conv10\_2, and conv11\_2 to predict both location and confidences. We set default box with scale 0.1 on conv4\_3<sup>3</sup>. We initialize the parameters for all the newly added convolutional layers with the "xavier" method [20]. For conv4\_3, conv10\_2 and conv11\_2, we only associate 4 default boxes at each feature map location – omitting aspect ratios of  $\frac{1}{3}$  and 3. For all other layers, we put 6 default boxes as described in Sec. 2.2. Since, as pointed out in [12], conv4\_3 has a different feature

# Single Shot MultiBox Detector

## Predictor的实现

**Convolutional predictors for detection** Each added feature layer (or optionally an existing feature layer from the base network) can produce a fixed set of detection predictions using a set of convolutional filters. These are indicated on top of the SSD network architecture in Fig. 2. For a feature layer of size  $m \times n$  with  $p$  channels, the basic element for predicting parameters of a potential detection is a  $3 \times 3 \times p$  *small kernel* that produces either a score for a category, or a shape offset relative to the default box coordinates. At each of the  $m \times n$  locations where the kernel is applied, it produces an output value. The bounding box offset output values are measured relative to a default

# Single Shot MultiBox Detector

## Predictor的实现

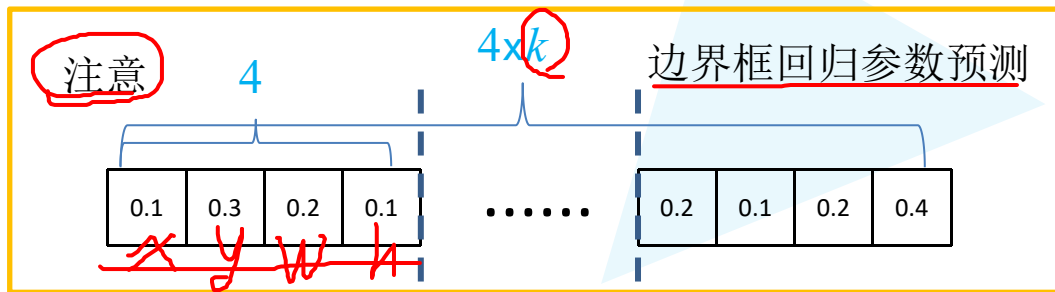

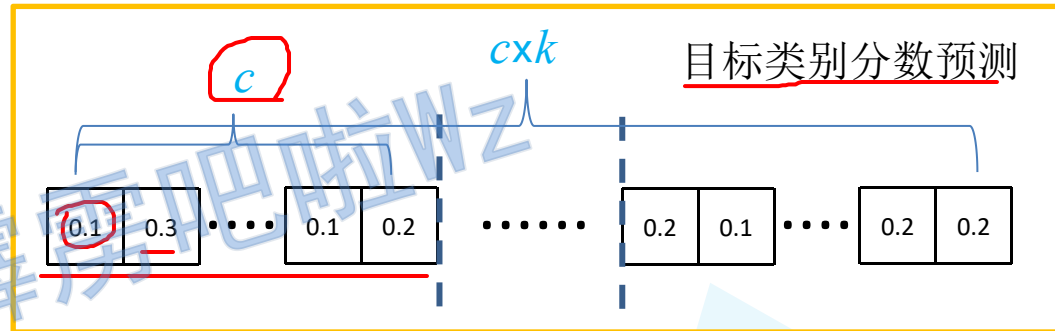

**Default boxes and aspect ratios** We associate a set of default bounding boxes with each feature map cell, for multiple feature maps at the top of the network. The default boxes tile the feature map in a convolutional manner, so that the position of each box relative to its corresponding cell is fixed. At each feature map cell, we predict the offsets relative to the default box shapes in the cell, as well as the per-class scores that indicate the presence of a class instance in each of those boxes. Specifically, for each box out of  $k$  at a given location, we compute  $c$  class scores and the 4 offsets relative to the original default box shape. This results in a total of  $(c + 4)k$  filters that are applied around each location in the feature map, yielding  $(c + 4)kmn$  outputs for a  $m \times n$  feature map. For an illustration of default boxes, please refer to Fig. 1. Our default boxes are similar to the *anchor boxes* used in Faster R-CNN [2], however we apply them to several feature maps of different resolutions. Allowing different default box shapes in several feature maps let us efficiently discretize the space of possible output box shapes.

# Single Shot MultiBox Detector

## Predictor的实现

$$(c + 4) \times k = \underbrace{c \times k}_{\text{目标类别分数预测}} + \underbrace{4 \times k}_{\text{边界框回归参数预测}}$$

# Single Shot MultiBox Detector

## 正负样本的选取

正样本

**Matching strategy** During training we need to determine which default boxes correspond to a ground truth detection and train the network accordingly. For each ground truth box, we are selecting from default boxes that vary over location, aspect ratio, and scale. We begin by matching each ground truth box to the default box with the best jaccard overlap (as in MultiBox [7]). Unlike MultiBox, we then match default boxes to any ground truth with jaccard overlap higher than a threshold (0.5). This simplifies the learning problem, allowing the network to predict high scores for multiple overlapping default boxes rather than requiring it to pick only the one with maximum overlap.

# Single Shot MultiBox Detector

## 正负样本的选取

### 负样本

**Hard negative mining** After the matching step, most of the default boxes are negatives, especially when the number of possible default boxes is large. This introduces a significant imbalance between the positive and negative training examples. Instead of using all the negative examples, we sort them using the highest confidence loss for each default box and pick the top ones so that the ratio between the negatives and positives is at most 3:1. We found that this leads to faster optimization and a more stable training.

# Single Shot MultiBox Detector

## 损失的计算

$$L(x, c, l, g) = \frac{1}{N} (\overset{\text{类别损失}}{L_{conf}(x, c)} + \alpha \overset{\text{定位损失}}{L_{loc}(x, l, g)})$$

其中 N 为匹配到的正样本个数， $\alpha$  为 1

(a) Image with GT boxes

(b)  $8 \times 8$  feature map

(c)  $4 \times 4$  feature map

# Single Shot MultiBox Detector

## 损失的计算

类别损失

$$L(x, c, l, g) = \frac{1}{N} (L_{conf}(x, c) + \alpha L_{loc}(x, l, g))$$

The confidence loss is the softmax loss over multiple classes confidences ( $c$ ).

$$L_{conf}(x, c) = - \sum_{i \in Pos} x_{ij}^p \cdot \log(\hat{c}_i^p) - \sum_{i \in Neg} \log(\hat{c}_i^0) \quad \text{where} \quad \hat{c}_i^p = \frac{\exp(c_i^p)}{\sum_p \exp(c_i^p)}$$

$\hat{c}_i^p$  为预测的第  $i$  个 default box 对应 GT box (类别是 P) 的类别概率

$x_{ij}^p = \{0, 1\}$  为第  $i$  个 default box 匹配到的第  $j$  个 GT box (类别是 P)

# Single Shot MultiBox Detector

损失的计算

定位损失

$$L(x, c, l, g) = \frac{1}{N} (L_{conf}(x, c) + \alpha L_{loc}(x, l, g))$$

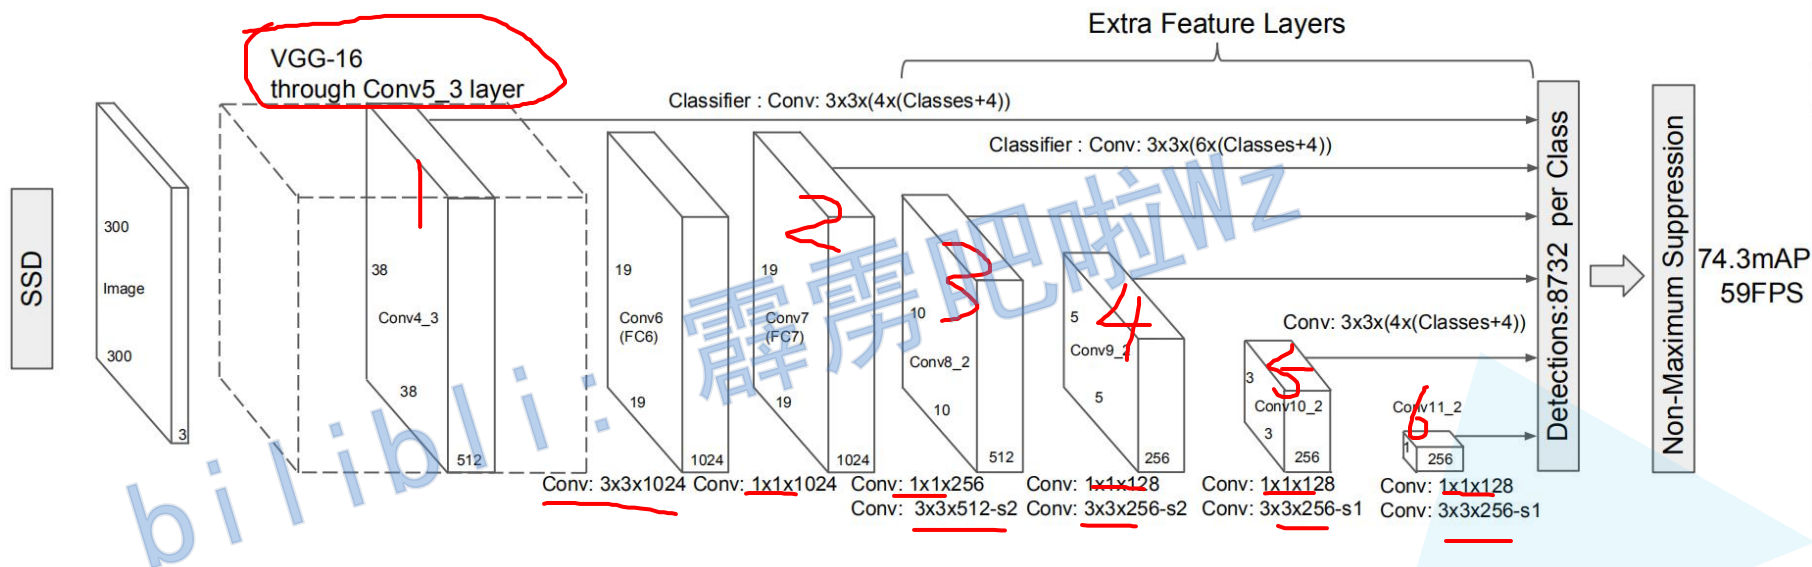

$$L_{loc}(x, l, g) = \sum_{i \in Pos} \sum_{m \in \{cx, cy, w, h\}} x_{ij}^k \text{smooth}_{L1}(l_i^m - \hat{g}_j^m)$$
$$\hat{g}_j^{cx} = (g_j^{cx} - d_i^{cx}) / d_i^w \quad \hat{g}_j^{cy} = (g_j^{cy} - d_i^{cy}) / d_i^h$$
$$\hat{g}_j^w = \log\left(\frac{g_j^w}{d_i^w}\right) \quad \hat{g}_j^h = \log\left(\frac{g_j^h}{d_i^h}\right)$$

$l_i^m$ 为预测对应第*i*个正样本回归参数

$\hat{g}_j^m$ 为正样本*i*匹配的第*j*个GT box的回归参数

$$\text{smooth}_{L1}(x) = \begin{cases} 0.5x^2 & \text{if } |x| < 1 \\ |x| - 0.5 & \text{otherwise} \end{cases}$$
